

The map reveals significant regional variation in California housing prices. The concentration of high pricing housing around the San Francisco Bay Area is likely associated with strong economic development, abundant employment opportunities, and the presence of major technology companies. These factors increase housing demand, while limited land availability further drives property prices upward.

Housing prices are highly concentrated in coastal metropolitan areas, particularly around the San Francisco Bay Area. Cities such as San Francisco, Oakland, and San Jose exhibit the highest median housing values, represented by the darkest red points on the map.

In contrast, the Central Valley, including Fresno, Modesto, and Bakersfield, has relatively lower housing prices, which are represented by the yellow and light orange points. Compared with coastal cities, these regions generally have lower population density, fewer high paying employment opportunities, and more abundant land resources, resulting in weaker housing demand and lower market values.

The map also reveals a clear pattern of geography. High pricing properties form continuous clusters around major economic centers, while lower pricing properties are predominantly distributed across inland regions.

Finally, the visualization indicates a gradual decline in housing prices from the coast toward inland California, suggesting that proximity to major metropolitan areas is strongly associated with higher property values.

Overall, this analysis indicates that geographical location is one of the significant factors influencing housing prices in California. Using QGIS can visually display the regional distribution characteristics of housing prices.
